Draft

1 Introduction

The Eastern Nile countries (EN), namely Egypt, Sudan and Ethiopia with the main interest in the sub-basins Baro-Akobo-Sobat, Blue Nile, Tekezze-Settit-Atbara, portions of the White Nile in Sudan, and the Main Nile are pursuing cooperative development at the sub-basin level through an investment oriented Eastern Nile Subsidiary Action Program (ENSAP). The proper development and management of these resources calls for an integrated approach within the framework of multi-country joint development program, which will address the opportunities and challenges within the basin in a unified manner that benefits all riparian countries. To this end, the Eastern Nile Council of Ministers (ENCOM) agreed to launch the first phase of identification of a major program of multipurpose development of the Eastern Nile just a year ago and proposed to prepare inventories containing information on the Water Resources, Environmental and Socio-economic issues for the EN.

In order to compile the Water Resources data from the Ethiopian side, a consultancy agreement was signed on 10th November 2005 between the Eastern Nile Technical Regional Office (ENTRO) here in after called the Client and Mr. Mesfin Shenkut of MS Consultancy here in after called the Consultant. The objective of this consultancy agreement is to compile essential information on water and related resources of the Eastern Nile sub-basins that will be used to support analysis for the identification of multipurpose development opportunities under the EN Multipurpose Development Program. The work also includes the preparation of a report on the data/information gathered, including comments on data quality, and annotated list of references

Based on the above, this report is presented as per the consultancy services requirements set out in the Terms of Reference (TOR) provided by the Client to present the draft report of the task of the activities undertaken by the Consultant. The report briefly shows the data collected and the general assessment of the data availability and quality as well as the drawbacks of the accomplished tasks. The collected data are annexed with this report.

1.1 The Basins

Ethiopia has been divided into twelve river basins. Among the river basins, the three basins, namely Baro-Akobo, Abby and Tekeze are located along the west and northwestern part of Ethiopia (see fig 1). They cover

an area of 358,072 Km² in total. Abbay takes the largest share with an area of 199,810km².

The basins have different potentials for water resources development. Taking the land and water resources together; Baro –Akobo has the largest irrigation potential, while considering water resource and hydropower potential Abbay is the most important basin in the country and Tekeze has got an immense potential of hydropower generation.

These basins are studied at different period and have fairly detailed pre-feasibility studies with complete master plan documents. For all of them, the amount of water available, the water resource development potential and the problems related within the river reaches have been studied.

Given the potential and the level of the available studies done, these basins are the least utilized basins in the country. Considering the booming population pressure, recurring drought and hunger with the demands for developing economy immediate response is required. Therefore, implementation of the master plan becomes the countries key question.

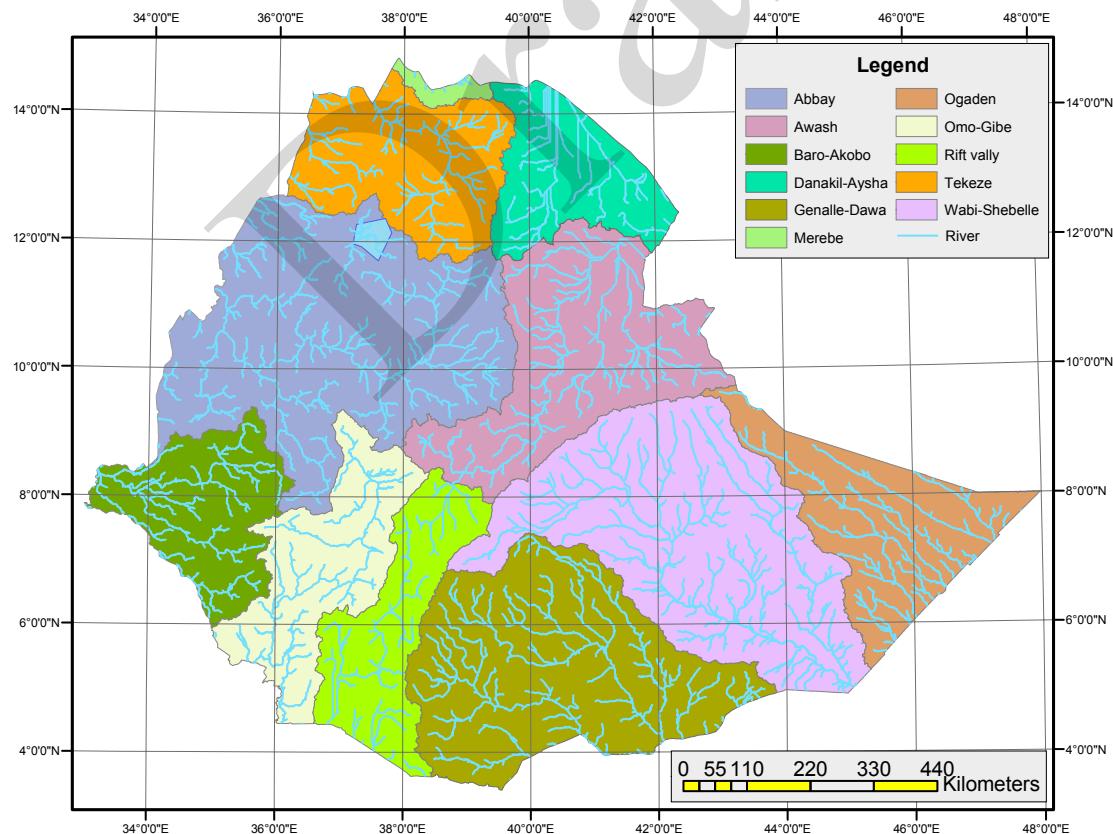

Fig. 1 Ethiopia's major river basins

1.2 Data Collection and Compilation

With the objective of compiling essential information on water and related resources of the Eastern Nile sub-basins that will be used to support analysis for the identification of multipurpose development opportunities under the EN Multipurpose Development Program, the data required have been categorized as per Table 1 of Annex 1. The Consultant has strictly adhered to the ToR provided by the Client and followed the format. The data categories are:

- o Basin Physical features
- o Hydrology and climate
- o Features of water infrastructure
- o Hydropower related
- o Irrigation and Navigation related

2 Data collected

Based on the format provided by the Consultant the following data have been collected and annexed in this report.

2.1 Basin Physical features

2.1.1 General

The data required here have been collected and processed to the required format .For these basins all the major features are prepared with both digital and paper format. It includes the main river network with the names labeled, identified projects i.e. irrigation and hydropower and location of infrastructures .There is also longitudinal profile for only the main stem Tekeze river but the quality of the data is not to the required level. The catchment delineated and the flow direction located in the map is comparable to the 1:2,000,000 scale map of the country.

The Consultant has concerns on the quality of these maps, because they have got considerable misalignment, especially the paper maps with the digital once. The state of art for collection of such kinds of data is new in Ethiopia. Data handling in general is poor. At the available data are mixed and in a few circumstances the accuracy of the data is not known even by the primary data holders.

2.1.2 Basin physical feature river network related

a. Major rivers, lakes and wetlands, and their basic features

All major rivers and lakes with their features have been indicated by the Ministry of Water Resources are attached in here. The consultant didn't find any previous study performed about wetlands.

b. River network maps (scale 1:2,000,000)

Form all the riparian countries in eastern Nile, most of the tributaries are in Ethiopia. Since all the river basins, namely, Tekeze, Abbay and Baro-Akobo have got lots of rivers networked and attached with them. The consultant tried to show the entire river network as compared with the related map produced by the Ethiopian mapping agency (EMA).

Here the consultant recommends satellite imagery digital elevation models are helpful to get more detailed map for the basin. And they can be co-referenced with the maps of EMA.

c. **Longitudinal profile of major river profile(scale 1:10)**

The longitudinal profile for all the main stems is not prepared in an appropriate format. Only paper based profile is available for Tekeze River, here also the accuracy of the data is questionable.

As it is already known, the longitudinal profile of river is one of the major inputs for identification of proper hydropower site. Here the Consultant recommends digitally processed satellite imagery to extract the profile with fair accuracy as an alternative.

2.2 Climate and Hydrology

2.2.1 Climate

2.2.1.1 Introduction

Basic climatic features of the Abbay, Tekeze and Baro-Akobo river basins are dominated by the near equatorial location, high altitude and the global scale mechanisms. The influence of these factors determine the variability of local climates ranging from hot and nearly desert areas to cold mountain peaks.

Since, much of the yield for the Nile River is contributed from the Ethiopian highlands; accessibility of these data has got a major significance in the study of any development work within the riparian countries. In fact in this basin, there are many stations within Ethiopia which measure rainfall and evaporation. However, most of the stations either show lack of records or wide recording gaps noted on the available data. In some instances the stations are either abandoned or are being restructured and upgrade their standards.

2.2.1.2 Precipitation Anomalies and Droughts

The largest source of moisture to the three river basins is the tropical Atlantic, which results in the main July-September rainy season. A minor source of moisture is the Indian Ocean which causes the small April-May rains. Sometimes these rains are less abundant and a drought

situation can arise. There are two distinct precipitation types. The monomodal and the bimodal type. Both the amount of precipitation and the distribution of the precipitation over the year could occur to cause a drought situation. In the past 30 years, several severe droughts have occurred in all the three river basins.

2.2.1.3 Climatological Data

The meteorological data are generally collected from the National Meteorological Agency. Some additional data have been collected by other Agencies, including the Food and Agriculture Organization, the Ministry of Agriculture and rural development, institute of Agricultural research and others.

Rainfall data are available in several stations in the three basins. The number of available years could be 2-40 years. Other climatic parameters such as mean maximum and minimum, temperatures, relative humidity, wind speed, sunshine duration have also been collected. Whereas some areas within each river basin have intense data coverage others have very low station density. Another short coming of the available data is the lack of daily data series.

a. Rainfall

This includes the mean annual rainfall isohyets with the rainfall record for selected fifty seven (57) stations. The mean annual rainfall isohyets and other parameters exist for all the basins but the Consultant has not included them here because of the compatibility problems with the original data. Out of the requested meteorological records for selected fifty seven stations, thirty eight (38) of the stations have got mean monthly rainfall records in mm. The general overview of the acquired data is tabulated in the Table below.

Considering the isohyetal map for the areas, the Consultant has accessed paper based maps on the master plan studies for the basins. For presentation purpose the isohyets are shown for Abbay basin in Fig 2.

From the data it is shown that for Tekeze and Baro- Akobo basin do not have much data available and the available data are not covering the reaches of the river evenly. Hence they are hardly showing the rainfall distribution for the basins.

Another alternative, like cold cloud determination (CCD) method which is used in the master plan study of Tekeze basin, can be used.

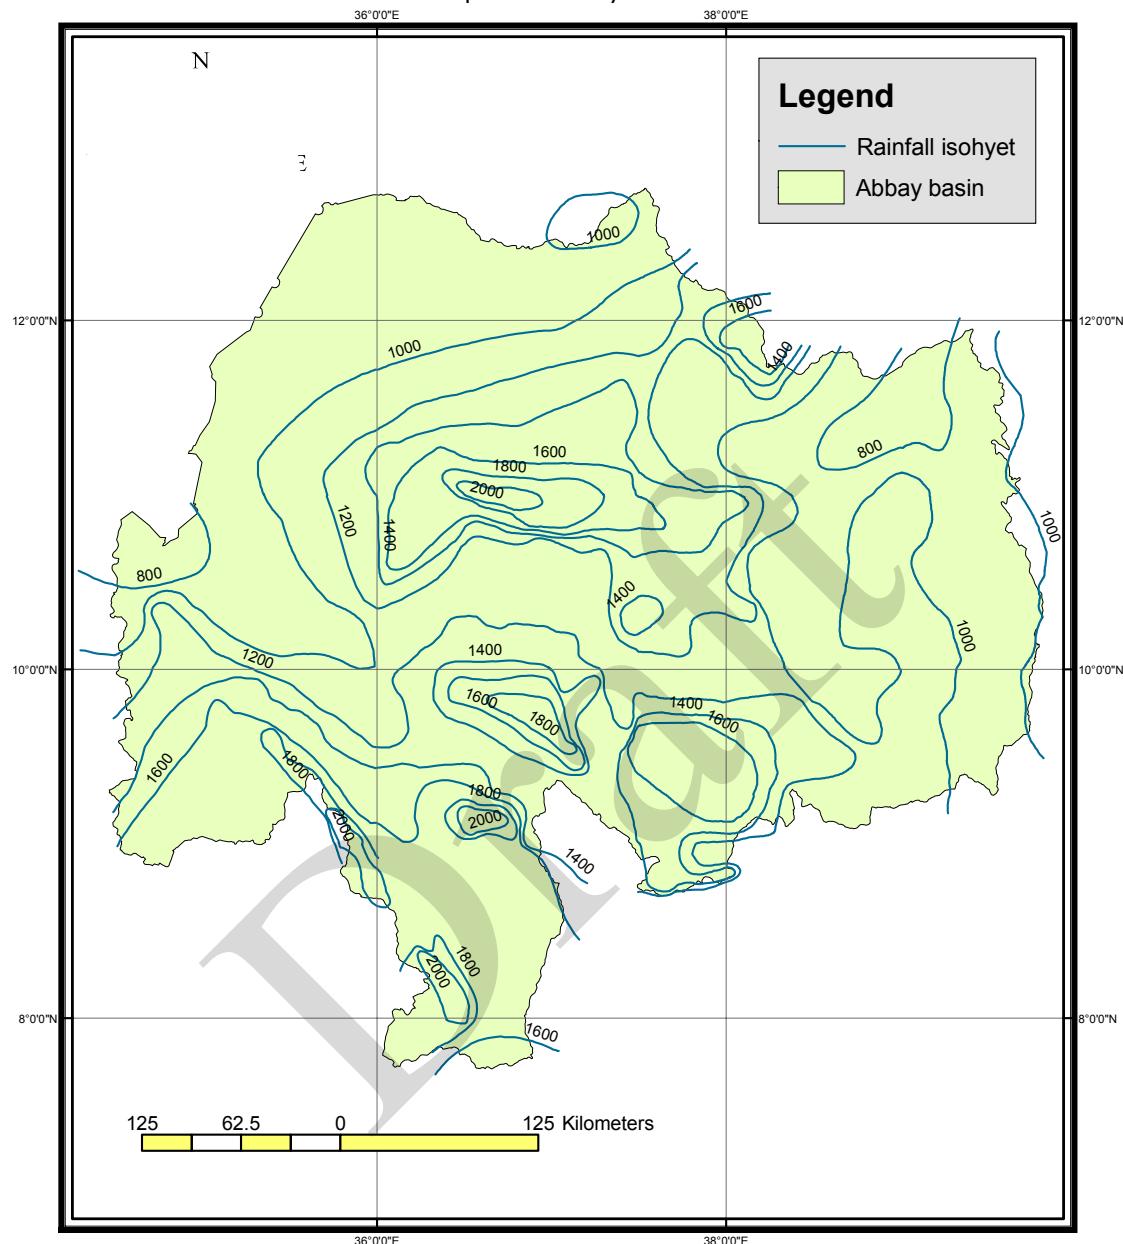

Fig. 2 isohyets for Abbay river basin basins

b. Evaporation

Though the expected data is to cover 57 stations and major reservoir sites, it is only 15 stations that the Consultant found information regarding direct measurement of mean monthly evaporation in mm. Other government documents and master plan studies use penman-monith method to determine the evapo-transpiration of the areas. This is also an option to determine evaporation indirectly. There is no isoline

of evaporation done for all the basins. General overview of the data with regard to their location, years they cover, and remarks on the quality of the data is summarized in Table 2.

2.2.1.4 Climatic Classification

The presence of lowland and highland areas closely associated over the river basins exerts a considerable influence on the climatic conditions. Most of the eleven principal climatic types of Ethiopia are distinguished in the three river basins ranging from hot semi-arid climate to cool highland climate.

Draft

2.2.2 Flow characteristic

a. Flow hydrographs

For the specified locations where data is required, most of the data are collected on monthly runoff volume basis with the exception of four of the sites. With a few exceptions these data are satisfactorily recorded. The general overview of the data quality is shown on table 3 below. The other data demanded such as river level and peak discharge in the basin could not be found.

There are general data gaps on records at border locations. Considering the importance these data for flood mitigation, determination of peak discharges and river level measurements is of immense importance.

b. Sedimentation

There are numerous gauging stations in the Baro-Akobo, Tekeze and Abbay river basins. The measurements have been taken over large range of discharges, and include measurements at high flows. Some of the measurements were taken at the beginning of the rainy season, when soil erosion and sediment transport are expected to be the highest due to the higher erodibility of the dry soil often deprived of vegetative cover. Estimates of soil erosion and land degradation are both difficult to achieve and are site specific. The situation is, however serious, especially in the cultivated areas. In such areas, losses of 1cm or more of soil each year could occur. This is well in excess of rates of soil formation.

The distribution of erosion potential in the maps prepared by the Abbay and Tekeze Master Plan Studies indicate the following:

None to Slight	<15 tons/ha/y
Moderate erosion	16-50 tons/ha/y
High erosion potential	51-200 tons/ha/y
Very high erosion potential	>200 tons/ha/y

A problem unique to the highlands of Ethiopia where the three basins are part occurs as a result of the widespread growing of teff, the staple cereal. The seed is tiny, about pin-head size, and so requires an extremely fine and level seed bed. This is accomplished by much cultivation which has an adverse effect on the soil structure.

For most of the stations selected, there are no data available and the Consultant collected the required information from alternative stations than those specified. This include sediment concentration, sediment load and sediment loss per day. The general overview of the collected data is shown in the following Table.

BARO-AKOBO

Gore	4	1988-1990,1996	1988-1990
------	---	----------------	-----------

3 Features of water infrastructure

The location of storage zones and other related reservoir and dam data are collected for all the basins. For most of the data collected, the infrastructures are studied on pre-feasibility stage or more including information on the purpose of the dams when they form part of the infrastructure. Both digital and hard copy data are available.

3.1 Hydropower related

Installed capacity and energy production and in some cases cost of production when available is collected for existing and planned hydropower schemes for the entire basin. In Abbay basin, only the Fincha-Amerti dam and the Chara – Chara high weir are exploited for hydropower purpose. In Tekeze river basin, the first hydropower dam is under construction at Tk-5. In Baro-Akobo basin, small amount energy is being generated. The dams for this purpose are designed and have preliminary cost estimates in the master plan studies (see Fig 3).

3.2 Irrigation

3.2.1 Introduction

Irrigation and drainage studies in the Baro-Akobo, Tekeze and Abbay river basins have been carried out at project specific and at regional levels. Irrigation sites have been identified. Some projects have been studied at feasibility level. The level of study in the remaining sites varies from identification to pre-feasibility level.

As stated in the master plan of the basins, Baro -Akobo has got the highest potential of irrigation while the Tekeze basin has little potentials for irrigation purpose (see Fig 4).

The basic scheme characteristics area and location are well presented in map and other relevant data are collected in spreadsheet format. Crop water requirement and cropping pattern is also collected as studied by government documents. The verification of the data to the actual condition has to be performed accordingly to present date.

3.2.2 Small Scale Irrigation

Small scale irrigation sites have conventionally been considered to be less than 200ha. The responsibility of small scale irrigation development has

recently been transferred from the Ministry of Water Resources to the Ministry of Agriculture and Rural Development. The problem with identifying and studying small scale irrigation projects is unavailability of suitable topographic maps.

Some studies however have been carried out in the Abbay and Tekeze river basins by the Tigray and Amhara Regional Governments. Estimates made by SAERT (Tigray Region) and SAERAR (Amhara Region). It has been considered that, spread over the entire Tekeze river basin, 1,500 reservoirs can be built over 30 years (May, 1998 estimate), providing a total storage of 1,500Mm³. Irrigation water demand calculations have been made to assess the size of irrigation development possible from a typical reservoir with a capacity 1Mm³ both in the Abbay and of Tekeze basins Master Plan Studies.

In the Abbay river basin, an estimated area of 100,000 to 150,000ha could be developed in small scale schemes. In the Tekeze river basin, in the year 2025, 450,000ha can be put under small scale supplementary irrigation. The small scale irrigation potential in the Baro-Akobo basin is restricted to the upper basin. Some 17 irrigation sites have been identified with a total area of about 120,000ha.

3.2.3 Large and Medium Scale Irrigation

Several large and medium scale irrigation sites have been identified in the Baro-Akobo, Tekeze and Abbay river basins. The total potential in the Baro-Akobo river basin exceeds 480,000ha. The potential in the Tekeze river basin is about 189,000ha. In the Abbay river basin, the potential is about 530,000ha for identified schemes.

Developing this potential would meet a number of constraints. Principal among these are lack of markets, lack of institutional capacity, limitation of private sector involvement and investment competition.

Rainfed cultivation area is difficult to estimate because the potential irrigable lands have existing rainfed farming or rainfed farming potential. Furthermore, the farming system requires large number of livestock and appropriate amounts of land need to be reserved for their maintenance.

3.3 Navigation

The Consultant has done different survey on this area and understands there is available data. But the data are not accessible one way or another.

Navigation however is limited to Baro Akobo basin while the other basins have steep slopes limiting any navigation activities.

Draft

4 PROPOSED PROJECTS

4.1 Introduction

Studies are being carried out on some Irrigation, Watershed and Hydropower projects in the Baro-Akoba, Tekeze and Abbay river basins.

The status of the studies is at different level. It ranges between pre-feasibility and detailed design.

4.2 Project Description

4.2.2 Hydropower Projects

4.2.2.1 Baro-1 & 2 and Genji Multipurpose projects (feasibility study)

i) Project Location

The Baro 1 and 2 MPPs are located along the Baro River in the Baro-Akobo Basin between Gore and Bonga, by road approximately 600 km west of Addis Ababa. The projects form a hydropower cascade, the tail water of the upper scheme (Baro 1) will be the headwater for the lower plant (Baro 2).

Genji River is a tributary to Baro River, with confluence some 3 km downstream of the Baro 2 dam site.

ii) Previous Studies on Baro 1MPP, Baro 2MPP and Genji Diversion

The hydropower potential of Baro River was first studied by TAMS & ULG in the "Baro-Akobo River Basin Master Plan Report" in 1996. A Pre-feasibility study for the Baro 1 and 2 MPPs was worked out by the Norplan-Norconsult Joint Venture in 1999.

iii) Objective of the Study

Baro 1 and 2 were intended to provide income and improvements in the region and create win-win situations for the countries of the Eastern Nile (Ethiopia, Egypt and Sudan).

iv) Project Characteristics

A. Baro-1 Project

The Baro scheme includes a reservoir with capacity for seasonal flow regulation. The Baro reservoir inundates approx 38 km² of rainforest.

- Total out put from the two units =180MW
- Catchments area = 2,210 km²
- Concrete faced rock fill dam (CFRD)

B. Baro-2 project

- Total output= 500MW
- Catchments area = 2,332 km²
- Rock fill dam with clay core

C. Genji Diversion Project

- Total output= 216MW
- Catchments area = 1,380 km²

4.2.2.2 Karadobi Multipurpose Project

i. Project Location

The Karadobi dam is located on the Abbay (Blue Nile) River, about 3km upstream of its confluence with Gudar River.

ii. Previous Studies

The site was investigated by USBR in 1963/64. The Abbay Basin master plan Project had also studied the project by upgrading the USBR study.

iii. Objectives of the Study

The major objective of the study is to establish reliable key data for the Karadobi Project by assuring whether the project is environmentally feasible.

iv. Project Characteristics

The project includes a high dam and a reservoir with improved regulation of the Abbay River.

Total output= 1600MW

Catchments area = 66,910 km²

Roller compacted Concrete (RCC).

4.2.3 Irrigation Projects

4.2.3.1 RIBB IRRIGATION PROJECT (Feasibility level study is in Progress)

i) General

The Ribb Irrigation Site has a gross area of 21, 123 ha of which 15,045 ha will be irrigated from a reservoir on the Ribb River. The annual water requirement for the irrigation area is 148.0 million m³.

The project will build a 53m high compacted rock fill and clay core dam on the rib river about 30km upstream of the river mouth at Lake Tana.

The main crop is rice which represents 60% of the cultivated area. With improvement mainly of drainage, flood protection and irrigation agricultural practices will change drastically.

ii) Project location

The Project area is located in Amhara Region, south Gonder Zone. The irrigable area is situated both sides of the Addis-Zemen-Wereta road and begins at a point of the river, 20 km east of the shore of Lake Tana where Ribb River approaches the lake plain from the mountainous area.

iii) Climate

The climate of the study area is marked by a wet season from May to September, with monthly rainfalls varying from 65mm in May to 411 mm in July. The dry season, from October to April has a total rainfall of about 8% of the annual rainfall of 1,295 mm.

Temperature variations throughout the year are minor (19.0°C in December to 23.0°C in May), whereas humidity values vary between 70% in December and 88% in August.

Wind speeds are low, thus minimizing potential evapotranspiration values between 95 mm/month in December and 140 mm/month in April. Sunshine duration is reduced to 6.0-6.5 hours during July to August.

iv) Accessibility

The lower part of the project area is traversed by the main Bahir Dar-Gondar road, whereas the southern part on the left bank is partly accessible from the Wereta Weldia main

road. The northern part or the right bank could be accessed from the Addis Zemen Debre Tabor road.

v) Soil Condition

Most of the area is waterlogged during the rainy season.

Measured infiltration rates on the Vertisols are in the range of 0.3-26.45 cm/hour. The measurement of infiltration rates on Vertisols was complicated especially by the presence of wide subsurface cracks. As a result higher infiltration rates were obtained.

Electrical conductivity values are very low, having values of 0.1-0.9 dS/m: therefore, salinity would not impose any limitation on plant growth. The flood plain soils (mostly Vertisols) have high levels of base saturation indicating a high fertility level.

In some areas close to the lake, the water table was found at a depth of about or less than 1 meter. All low lying and depression areas are excluded from the proposed scheme. On the contrary, the soils of the steeper area are excessively drained.

vi) Hydrology

Irrigated agriculture in the valley would depend on water available from the Ribb River and on the possibility of drainage which is influenced by Lake Tana.

Without dam, average flows of Ribb River decrease from a maximum of 31m³/s in August to a low 0.39 m³/s in April. Dry season flows, exceeded 4 out 5 years reach minimum values 0.09m³/s.

Lake levels vary between +1784 and + 1787.5 and especially during flood flows and high lake levels the project areas in the lower reaches of the valley would face drainage problems.

vii) Irrigation and Drainage

The maximum duty would amount 0.6 and 1.1 l/s.ha, respectively for the non rice based cropping pattern and the rice based cropping pattern.

For preliminary design purposes, it has been assumed that 50% of the irrigated area would be covered by the rice based cropping pattern with the remainder for the no rice system. Hence the average duty that has been adopted for the calculations is 0.85 l/s/ha/

viii) Conveyance and Distribution Systems

Water would be diverted by a 70m long concrete weir, with its crest at 1801.0m into a sedimentation canal with a length of 800-900m. The capacity of the weir at free flow has been calculated at 180m³/s, equivalent to a water level of about +1801.8 in the river just downstream of the weir. Full bank flow just upstream of the weir amounts to about 400 m³/s.

Flood flows which overtop the embankment upstream of the weir would be diverted to the 150-200 m wide floodway to the north of the weir. In order to prevent erosion on downstream banks in the vicinity of the weir, the design of the weir has taken into account that once this floodway starts to operate the river downstream is at full bank.

4.2.3.2 MEGECH IRRIGATION PROJECT (Feasibility Level Study is in Progress)

i) General

The Megech irrigation area has a gross suitable area of 13,100 ha, of which 10,018 ha will be irrigated. The project will pump water from Lake Tana, thus there is no reservoir associated with the development. Annual water extracted will be 86.8mm³.

Water would be supplied via pumping stations at the eastern and western extremities of the project area with capacities of 4.6m³/s and 3.7m³/s respectively, at dynamic heads of 15.6m and 15m respectively.

ii) Project Location

The project area is located in Amhara Region South Gonder Zone. It is located in the northern portion of the Lake Tana sub-basin and has a catchment basin of about 700km². The river flows generally in a southerly direction towards Lake Tana. The main tributaries of the Megech are the West fork and the Angerb. The project area is on the lake plain south of the Gondar-Debre Tabor road and begins at a point about 15 km north of the lake where the river breaks out of the steep canyon area into the lake plain

iii) Climate

The climate of the project area of East and West Megech is marked by a wet season from June to September, with monthly rainfalls varying from 155mm in May via 271 mm in July to 115mm in September.

Data have been taken from Gorgora station. The dry season, from October to May has a total rainfall of about 14% of the annual rainfall of 906 mm.

Average daily temperature variations throughout the year are minor (19.0°C in December to 23.0°C in May), whereas humidity values vary between 77% in February and 88% in August. Wind speeds are low, thus minimizing potential evapotranspiration values between a low 95mm/month in December and a high of 141mm/month in April.

Sunshine duration is reduced to 6.0-6.5 hours during July/August.

iv) Accessibility

Access to East Megech is possible via a track departing from the main road Gondar-Bahir Dar, 1km south-west of the village Maksenyit. Access from kola Diba is impossible due to lack of bridges or drifts across the Megech River.

Access to the West Megech is possible from kola Diba and Gorgora. However, during the rainy season the area is inaccessible as most tracks are on Vertisols which are rendered impassable even after the slightest rain. Apart from Gorgora, there are no harbours or landing facilities.

v) Soil Condition

In some areas close to the lake, the water table was found at a depth of about or less than 1 meter. All low lying and depression areas are excluded from the proposed scheme. On the contrary, the soils of the steeper area are excessively drained.

Measured infiltration rates on the Vertisols are in the range of 1.6-3.8 cm/h, whereas the red soils show rates of 8.8-16.5cm./hour.

Electrical conductivity values are very low, having values of 0.1-0.7 dS/m and therefore, salinity would not impose any limitation on plant growth. The flood plain soils (mostly Vertisols) have high levels of base saturation indicating a high fertility level.

vi) Hydrology

Development of irrigated agriculture in the valley would depend on water available from the lake and on the possibility of drainage which is influenced by Lake Tana. Drainage would have to be provided to prevent water

logging during the wet season. Lake levels vary between +1784 and +1787.5.

Over bank flow from Megech River tends to flood areas along the riverbed and therefore flood protection dykes have to be constructed. The present dykes are directly along the watercourse and have very steep banks. Therefore, they are not adequate.

vii) Irrigation And Drainage

The maximum duties amount to 0.74 l/s.ha for the cropping pattern without rice occurring in March and to 1.16 l/s.ha for the rice based cropping pattern, occurring in January during land preparation.

viii) Conveyance And Distribution systems

At full development, the pumping station would have a capacity of 4.6m³/s (0.7 l/s.ha), with an installed power of about 1.3 MW in 4 units, including 1 standby unit at East Megech. The number of 250KVA transformers would be 5. Water would be lifted over 13.5m. With 3 steel pipelines with 1.0m diameter and 260m long the dynamic head would be 15.6m at a velocity of 1.95 m/s. Annual operating hours would be 2, 906, whereas 2.7 GWh are required to lift 48 MCM during an average year.

At full development, the pumping station would have a capacity of 3.7 m³/s (0.7 l/s.ha), with an installed power of about 1 MW in 4 units, including 1 standby unit at west Megech. The number of 250 KVA transformers would be 4. Water would be lifted over 13.0m. With 3 steel pipelines with 1.0m diameter of 110m long the dynamic head would be 15.0m, at an average velocity of 1.60m Annual operating hours would be 2,906, whereas 2.1 GWh are required to lift 39 MCM during an average year.

4.2.3.3 NORTH EAST TANA LAKE IRRIGATION PROJECT (Feasibility Level Study Is In Progress)

1. General

This is a relatively small irrigation site of 5,000 ha. Development opportunities are good, because of the presence of ample water of good quality in Lake Tana, Soils with good fertility and a good topography, reasonable infrastructure, relatively good marketing facilities and the presence of a large farming community.

2. Project location

The project area is located in Amhara Region South Gonder Zone. The land areas considered are located on the lake plain on Northeast shore of Lake Tana, extending from Mitraa Island southwards to the edge of Ribb River valley. The area is about 14km in length and from 2 to 6 km in width. The main road from Gondar to Addis Zemen passes very near the North East limit of the project area.

3. Climate

The climate of the study area is marked by a wet season from June to September, with monthly rainfalls varying from 175mm in June via a maximum of 449 in August to 176 in September. The dry season, from October to May has a total rainfall of about 12% of the annual rainfall of 1,354mm.

Temperature variations throughout the year are minor (minimum of 18.70C in August to a maximum of 23.0oC in April), whereas humidity values vary between 77% in May and 88% in August. Wind speeds are low, thus minimizing potential evapotranspiration values between 95mm/month in November/December and 140mm/month in March. Sunshine daily duration is reduced to 6.0-6.5 hours during July/August.

4. Accessibility

The northern area, can be reached via a track, taking-off from the main road Bahir Dar-Gondar just north-west of the crossing with the river of Arno garno. The 15km long track which has been used by trucks collecting sand from the lake shore is motorable during the dry season. There are many dry season tracks but numerous stream crossings render them impassable for most of the year.

5. Soil Condition

The majority of the soil can be classified as heavy clay soils, with impeded drainage. Ground water was found at a depth of more than 2.00m measured infiltration rates on the Vertisols are in the range of 1.0-17.7cm/hour.

Electrical conductivity values are low, having values of 0.1-1.2dS/m and therefore, salinity would not impose any limitation on plant growth. Most of the soils (Vertisols) in the study area have high levels of base saturation indicating a high fertility level.

6. Hydrology

Irrigation water would have to be pumped from Lake Tana, where levels vary between +1784 and +1787.5. During high water levels low areas along the coast line would be flooded whereas other areas might face drainage problems.

The lowest areas (classified as swamp and wet land) all along the lake shore which are presently used for grazing should be kept for this purpose: they are totally excluded from the scheme.

7. Irrigation and drainage

The maximum duty of the irrigation systems amount to 0.76 l/s.ha and 1.19 l/s.ha respectively for the without and with rice cropping patterns. Field irrigation methods include furrows for row crops and basins for rice and other crops. At this stage it is not appropriate to select alternatives but taking into account the presence of heavy soils, basins and furrows would be the preferred methods.

8. Conveyance and Distribution Systems

Water would be lifted by electrically driven pumping station from a minimum level of +1784 via a 1 km long rising main to the village of Gbeta Mewcha which is located at 1800-1810m, in a saddle in the hill range. The pumping station would have a capacity of 1.61m³/s against a dynamic head of 22m, requiring a minimum power requirement of 416 kW.

4.2.3.4 GILGEL IRRIGATION PROJECT (Feasibility Level Study Is In Progress)

1. General

The proposed irrigation system is made of two independent areas along the Gilgel River. The report is made separately for the two schemes Gilgel 2 and Gilgel 5. Either Gilgel 2 or Gilgel 5 could be implemented before the construction of the dam. Gilgel 2 would require a diversion weir while Gilgel 5 requires a pumping plant. The total command area is 5496ha.

2. Project Location

The project area is located in Amhara Region, West Gonder Zone. The right bank is part of Merawi Wereda, with Merawi as administrative centre.

3. Climate

The climate of the valley falls in the traditional Woina Dega climatic zone and is marked by a wet season from May to September, with monthly rainfalls varying from 123mm in May to 430mm in August. The dry season, from October to April has a total rainfall of about only 10% of the annual rainfall of 1,572mm.

Temperature variations throughout the year are minor (15.7°C in January to 18.2°C in May), whereas humidity values vary between 58% in May and 80% in August.

Wind speeds are low, thus minimizing potential evapotranspiration values between 95 mm/month in August and 144 mm/month in April. Sunshine duration is reduced to 3.6-5.2 hours daily during June to August; combined with low temperatures.

4. Accessibility

The Project Area is poorly served by roads and tracks. During the rainy season it is impossible to reach the projects sites by vehicle, apart from the site near Chimba.

5. Soil Condition

The soils are mainly Vertisols. Ground water in the floodplain is generally found at shallow depth; however, during surveys it has rarely been found at a depth less than one meter. On the contrary, soils of the steeper area are excessively drained. Measured infiltration rates on the Vertisols are in the range of 1.6-3.8cm/h, whereas the red soils show rates of 8.8-16.5cm/hour.

6. Hydrology

Development of irrigated agriculture in the valley would depend on water availability from Gilgel River and on the possibility of drainage which is influenced by Lake Tana.

Without dam, average flows of Gilgel River which has a catchment area of 1,980 km² at the gauging station just upstream of the main road crossing at Wetet Abbay would decrease from a maximum of 193 m³/s in August to as low as 3.1 m³/s in April. The dry season flows, exceeded 4 out 5 years reach minimum values 1.7m³/s.

7. Irrigation and Drainage

The maximum duty of the irrigation systems amount to 0.69l/s.ha and 1.18 l/s.ha respectively for the without and with rice cropping patterns. At this stage field irrigation methods are not appropriate to select appropriate alternatives but taking into account the presence of heavy soils, basins and furrows would be the preferred methods.

8. Conveyance and Distribution Systems

Piped off takes from the dam will supply by gravity water to the main canals in right and left bank, at elevation 1,860. The right bank canal is 16.8 kilometers long of which 44% must be lined;

A pumping plant with a capacity of 1.7m³/s for a dynamic head of 20 meters will be constructed.

5 Major issues in water resources development and management in Ethiopia

The three basins cover nearly one third of the total area of Ethiopia and accounts for 65 percent of the country's estimated annual water resources as well as affects 39% of its population. The flow from Ethiopia provides over 80% of the water for the two countries.

Frequently, the country is subjected to food shortage and recurrent drought. This coupled with the alarming population; there is the need to develop the irrigation potential. As part of Eastern Nile basin the country and the MDG goals, high priority should be given to mitigate the problem. Therefore, the implementation of the studied potential irrigable areas needs to be given immediate attention.

The three basins have immense and untouched potential of hydropower. This is believed to enhance economic growth. Despite these huge untapped resources, it is only 13% of the Ethiopian people with access to some sort of electricity. This is again area of big attention.

5.2 Flood Situation

5.2.2 Introduction

The flood studies in the Abbay, Tekeze and Baro Akobo river basins are mainly to establish values of design flood at the locations of various projects. Generally, dam spillways are designed to pass the 1,000 year or 10,000 year flood. The villages and towns are required to be protected against 10-year or 20-year flood. Irrigation projects are also protected against the 10-year or 20-year flood. Some enclaves and depressed areas are prone to flooding. In the highland parts of the three river basins, rivers cut their channel deep in to the volcanic cap and the underlying sedimentary rocks. Floods usually occur once the rivers reach the level land.

5.2.3 Flooded Areas

The Gambella plain in the Baro Akobo River Basin has been partly under flood.

There are two reasons for the flooding problem of the Gambela plains.

- Flooding resulting from overflows of river banks; and,
- Flooding resulting from rainfall and poor drainage.

The flooding resulting from the river overflow is stated as the consequences of two possible phenomena: a river bankfull capacity too small and the backwater effect from the Pibor River and the Sobat River.

Flooding in the Gambela Plain varies from year to year. For each flooding situation the Study has estimated the probability of the land flooding. The total area of the lower basin subject to repeated flooding is 9720 km².

5.2.4 The Proposed Flood Protection Measures

There are essentially two possible flood protection measures proposed by the Master Plan Study for the Gambela Plain.

These are:

- construction of dikes to prevent the over topping of river banks; and,
- Construction of reservoirs to store and control the runoff from the upper watershed.

The Master Plan Study proposes the construction of dikes, drains and pumping stations for the protection of the towns of Gambela and Itang. The protection of Gambela consists in building 2.4 km of dikes along the right bank of the Baro River and its right tributary the Jejebe River with a five-meter wide road on the crest.

The second approach, which consists of providing flood control storage capacities at dams upstream of the considered developments, should also be evaluated on its economical merit. In the case of the Gambela plain due to the complexity of the flooding process and the large number of unknown factors, it is uncertain that this approach is practical.

The flooding of the plain is caused by a combination of events for which there are very few known facts, including the flooding of the Pibor river which forms the border with the Sudan and the limited capacity of the Sobat river downstream of the Pibor in the Sudan.

6 Drawbacks

The above data collection and compilation was seriously hampered due to the following problems:

- The data holders are not fully committed to give appropriate data and access to data sources. Lack of awareness and poor coordination among the data holders is prime cause for the problem.
- In some of the cases especially, maps and related information, the data are not fully dependable and
- Most of the available data is highly unstructured and the primary data and the secondary data are mixed or regenerated after the original data are completely destroyed.

7 Annotated list of references

BCEOM ; 1998, Abbay River Basin Integrated Development Master Plan, Ministry of Water Resources Addis Ababa, Volume I - XVIII, Main Report, Executive Summary, Annexes and Master Plan (Volumes I-IV)

Basin Physical Features

7.2 River network related

The report discusses the surface water including the river network. The river network of the basin is dominated by the Abbay, which rises in the centre of the basin and develops its course in a clockwise spiral.

The river network data covers tributaries, catchment area, flow direction, average annual discharge, lakes, wetlands and their basic features. The spatial representation includes river network maps and longitudinal profile of major rivers.

The Abbay collects water from enormous tributaries before reaching the Sudan border above the Reseires dam. The Gilgel Abbay, the main river flows north from its source into Lake Tana. The lake receives tributaries from a catchment of 15,320 km². Tributaries are acquired on the right and left banks.

The text and the maps are well elaborated. The average annual discharge as well as their low flow and high flow months. The data has been to a large extent utilized. Most of the rivers are gagged and long years flow data are available.

7.3 Hydrology and Climate

7.3.2 Climate

Data are available until 1998. Hence the latest data from the National Meteorological Service Agency (NMSA) utilized.

7.3.3 Flow characteristics

Available hydrographs at selected points have been utilized.

7.3.4 Sediment transport measurements, sediment loads.

The report summarizes observations based on previous assessments (before 1998). The annual sediment discharge and sediment yield assuming a 10% delivery rate to the rivers. One of the Major sources of sediments is erosion of the intensively farmed high land areas in the central and eastern parts of the basin (about 100 t/ha/yr rate for the basin).

7.3.5 Flood peaks at selected points

Available from the Hydrology Department of the Ministry of water Resources.

7.3.6 Existing Water Infrastructure

This aspect has been discussed with minimum data because of the low economic development level of the basin.

7.3.7 Water Resources Opportunities

The report discusses the identified sites at reconnaissance and semi detailed level. The pre-feasibility studies have been documented in separate volumes. A good part of these data has been utilized. Only part of the identified sesames have been taken to the pre-feasibility level.

7.3.8 Major issues in water resources development and management in the EN.

Data for flood damage have not been well documented in the Master Plan reports.

**NEDECO, 1998, Tekeze River Basin Integrated Development
Master Plan, Ministry of Water Resources, Addis Ababa,
Volume I-XX and Executive Summary.**

1. Basin Physical Features

River network related

The report details basic features of the basin including the drainage system. The basin has an average elevation of 1850 masl and a catchment area of about 59,306 km². The basin includes the Angereb (area about 13,327 km²) and Guang (area about 6,694 km²) sub-basins.

2. Hydrology and Climate

2.1 Climate

The study discusses the general characteristics the climate of the basin, anomalies and variability of climate, precipitation, station network, missing data, rainfall from satellite data and evapotranspiration some 6 maps have also been provided attached to the report.

The study also provided analysis for drought. The consultant used patched rainfall series in and near the study area that had 20 or more years of observations. From each series the number of meteorological droughts were determined. Meteorological drought is defined as rainfall with an annual probability of 20% or less. It has been concluded that the number of drought to has been increased in the 1980-1994 period in comparison with the 1965-1979 period.

The report also discussed augmentation of rainfall data using satellite information. Since 1992, National Meteorological Service Agency (NMSA) has been publishing 10 day, monthly, seasonal and annual precipitation estimate maps of Ethiopia, based on Cold Cloud Duration (CCD) data. CCD data are temperature data of the cloud tops. Cold (high) clouds can be associated with rainfall, assuming that they are the tops of the active storms. CCD data can be obtained from satellite data. At present the satellite data required for rainfall estimation are obtained by NMSA from METEOSAT (the European geostationary satellite a Primary Data Users System (PDUS)).

The study further analyzed several climatic elements including temperature, wind speed, sunshine hours, radiation and relative humidity. They have a much smaller spatial variation, which means that fewer stations are required to obtain good regional estimated.

The climate data, however was largely obtained from the National Meteorological Service Agency (NMSA) were utilized for the present study. This is because the data contained in the report were collected before 1998.

This study provides the data required on river flows over time and at the specific locations in the basin. The master plan project has initiated improved monitoriver by assisting and procuriver materials for station upgrading, designing stilling wells, and procuriver new flow measuriver equipments.

The hydrometric network (1996) consists of 30 stations of which 14 have recorders. The report also discusses station operation and data processing by the Hydrology Department of the Ministry of Water Resources. The study states that the Regional Governments have staff and budget constraints, which affect the adequacy of flow gauging. It was stated that the historical flow data in the Tekeze basin have a very short record length (max. 10 years).

The flood studies indicate that high flows in the basin are the results of wet season high precipitation. They mainly occur July to September. Flood hydrographs related to the highest peaks have been prepared. Several flood calculation methods have been provided. Catchment yield for the basin has been determined after considerate factors influencing the flow rate and yield. The average specific sediment yield of the basin area is 900 t/km²/year.

The study annexed the following:

- Monthly discharge data
- Rating equation preparation and flow calculation
- Daily weighted average water levels and daily flows
- Monthly flows
- Hydrological stations
- Flow data used for verification of the generated flows
- Generated flows for dam sites
- Flood calculation methods
- Surface water quality data
- Sediment data

The maps included:

Hydrological map

Hydrometric stations

For optimal use of the surface water in the basin, hydrologic monitoriver will have to be considerably improved.

Available hydrographs at selected points have been utilized.

2.2 Sediment transport measurement sediment loads

The report discusses the erosion potential of the basin including sediment transport and loads. Trends are observed putting the basin area in a situation of accelerating deterioration of natural resources.

- population increase
- limited buffer capacity of many areas to withstand degradation
- ongoing depletion of vegetation and nutrient missing farming systems

Though the above information has been accessed the consultant collected primary data from the Ministry Water Resources. Refer to Table 5 above for details.

2.3 Flood peaks at selected points

Monthly runoff volume has been obtained from the Ministry of Water Resources; hence the flood peak could not be identified.

3. Water resources opportunities

Dams selected by the project for further study include TK04, and TK07 in the middle Tekeze River. TK21 in the Angereb River and TK22 in the Genda River. Potential Negative effects of the dams are related mainly to water borne and transmittable diseases and changing water regimes.

The potential for irrigated agriculture has been addressed in this document. Relatively detail study has been done in this document.

4. Major issues in water resources development and management

As there is no big threat as regards to flooding, no emphasis given in the document.

**TAMS - ULG, 1997, Baro Akobo River Basin Integrated
Development Master Plan, Ministry of Water Resources, Addis Ababa
Volumes I - V, and Annexes 1- 4**

1. Basin Physical Features

- River network related

The major rivers within the basin are the Baro and its tributaries (Birbir, Geba, Sor, Alwero and Akobo). The basic data used by the master plan study include monthly river discharges at various gauging stations and monthly precipitation. The general direction of the rivers is from the east to the west. The rivers originate in the highlands (2000-3400 masl). All the major rivers are gauged.

2. Hydrology and Climate

2.1 Climate

The meteorological data were collected and processed by NMSA. The data contained in the master plan were, however, not used because of their collection before 1997. Latest data from NMSA were used in this study.

2.2 Flow Characteristics

The observed monthly data by stations are provided in the Master plan report. The flow fluctuation of the observed monthly flow data are high: The coefficient of variation is close to one.

The data for the present study however were obtained from the Hydrology Department of the Ministry of Water Resources.

2.3 Sediment transport measurements, sediment loads

The amount of sediment that enters and accumulates in the reservoirs planned for the basin have been studied. Based on the estimates reservoir dead storage was selected.

2.4 Flood peaks at selected points

The magnitude and frequency of the floods in the rivers on the basin have been estimated in order to provide data for the design of spillways for hydropower and irrigation dams and of flood protection works for towns and villages, especially in the Gambella plain.

The flood studies in the basin are the most elaborate than the other master plan studies. The flood damage data however are not available also for this basin.

3. Water Resources Opportunities

The study concluded that the Baro-Akobo Basin contains a very high potential for both hydropower and large scale irrigation development. A number of hydropower and irrigation schemes have been studied to pre-feasibility level.

4. Major issues in water resources development and management in the EN.

The environmental issues include the location of the large scale irrigation projects in the wildlife habitats.

Ministry of Water Resources

Hydro-Sedimentological Data Base of h Project "Monitoring and Assessment of Erosion and Sedimentation in Ethiopia"

Daily Observation

Station number	112007	GUIDE:
River basin	Abbay	1. Save the file under the new name (name of site) into the folder with the name of the river ! 2. Clear the old data with:mark, Edit, Clear, Contents Del 2. Fill the data of the HSD (Ato Wondimu) in the fields with the following color: 3. Add an empty row between measurements of non following days
Station name	Debre Birhane	
River	Beressa	4. Copy the automatically computed values for Water discharge and sediment load in the co
Catchment area (km ²)	211	(File name: input1)
Transformation equation	$g=20.52(h-0.25)^{2.5}$	

Year	Month	Day	G.H. h (m)	Flow Q (m ³ /s)	Daily discharge m ³ /d	Sediment concentration g/t mg/kg ppm	Sediment concentration g/m ³ mg/l	Daily sediment load t/d

SEDIMENTATION

Draft

Ministry of Water Resources

Hydro-Sedimentological Data Base of Project "Monitoring and Assessment of Erosion and Sedimentation in Ethiopia"

Daily Observation

Station number	0-101007	GUIDE:
River basin	Baro-Akobo	1. Save the file under the new name (name of site) into the folder with the name of the river basin 2. Clear the old data with:mark, Edit, Clear, Contents Del 2. Fill the data of the HSD (Ato Wondimu) in the fields with the following color: 3. Add an empty row between measurements of non following days
Station name	Gore	
River	Gumero	
Catchment area (km ²)	100	4. Copy the automatically computed values for Water discharge and sediment load in the columns O and P (File name: input1)
Transformation equation	$g=20.52(h-0.25)^{2.5}$	

Year	Month	Day	G.H. h (m)	Flow Q (m ³ /s)	Daily discharge m ³ /d	Sediment concentration g/t mg/kg ppm	Sediment concentration g/m ³ mg/l	Daily sediment load t/d	Sediment loss kg/km ² day
